
The window title

- If Steam is not running, the window title will contain “**Steam not detected**”. In this case, all Steam related functionality will be disabled and mods downloaded from the Workshop will show up as “**missing**”.

The menu bar

- **Go to Workshop**: opens the Steam Workshop page for The Guild 3.
- **Add path**: you can manually specify a path for a folder mod. Verification will be performed, and if it fails, and error message will be displayed. In case of no errors, the mod will show up in the mods section.
- **Add folder**: same as above, but using a standard folder selection window.
- **Create new mod**: choose (or create) an **empty** folder to create a new mod. A “content” subfolder and some other files will be auto-generated for an easier Steam Workshop workflow.
- **Create new scripting mod**: same as above, but the media folder will be pre-populated with the default scripts. See modding advices at the end of this document.
- **Disable all**: disables all mods in the mods section.

The selected item section

- **Unsubscribe / Remove**: in the case of a Steam Workshop mod, this button will unsubscribe you from the mod, and remove it from the mods section, otherwise (folder mod) it will remove the mod from the mods section, but it will not delete it from your storage device.
- **Mod files**: opens an explorer window with the contents of the mod.
- **Go To Workshop**: opens the Steam Workshop page for the mod. (Steam Workshop mods only!)
- **Disable / Enable**: disables / enables the mod for deployment.
- **Play**: this button will only show if you select the game itself. Verification of possibly overlapping mods will be performed, and an error shown if there's a conflict. Make sure you disable all mods you're not using, and also disable or remove the ones that show up as "**missing**".

The mods section

- Mods are listed top to bottom in order of deployment. Red colored lines (also showing up as "**missing**") means the system either can't find the mod, or in the case of a Steam Workshop mod, Steam is not running. You can change the deployment order by drag'n'droping the lines. Clicking a line will display its details in the selected item section above.

Modding advices

- Create a new mod using either of the buttons, depending on the mod type. Use the "**Create new scripting mod**" button for script mods, as it will extract the default scripts for you. In case you're only uploading custom maps, just use the "**Create new mod**" button, and place your maps into the "**Maps**" subfolder.
- Replace "**preview.png**" with any image you'd like to use for your mod in the Steam Workshop.
- Read "**TG3 - Script Documentation**" on how to modify scripts and values.
- In case your modifications take no effect, make sure your mod folder contains the "**Media**" folder within it, and the scripts are properly modified. Do not delete any files, even if you haven't modified them.

- If you get an error window saying "**Script error**", press OK, and let it run until it quits by itself, or exit manually from the main menu. Check the contents of "**scripts.log**" which will be in the root of the specified mod folder.
- You can launch the game with the command line option “**-asserts**” to receive more runtime information about the problems of the map / scripts. This may give you “false alarms” that are not errors just warnings, so make sure you read the message. You can choose “**continue**” to resume the game.
- You can find a freshly created “**publish_mod.bat**” file in the folder you’ve specified. This will publish the mod to the Steam Workshop, only visible to you by default. In case of successful publication, a new “**update_mod.bat**” will be created, which enables you to update the contents of the mod in the workshop from the same folder.
- If the game is detecting your mod, an ID of it will be displayed on the loading screens and the main menu. Multiplayer games are only allowed with people having the same exact ID on their screens.

Creating a new mod manually

- Create an empty folder. It must contain either a “**Maps**” or a “**Media**” subfolder, or both.
- Put your custom maps into the “**Maps**” subfolder.
- If you’re doing a scripts mod, unzip "**guild3_scripts.zip**” to the mod folder. Make sure you preserve the "**Media**" folder and the structure within it. Do not delete any files, even if you haven't modified them.
- Test your changes by starting the game with this command line option: Guild3.exe -mod <path_to_the folder>

The uploader tool

- **Skip this section if you're using the Mod Launcher, it will do everything for you automatically.**
- The Guild3ModUploader.exe is used to publish / update mods in the Steam Workshop. It has two modes: when you first introduce the mod to the Workshop, you "publish" it, any subsequent modifications of the same mod happen in the "update" mode.
- Publishing: Guild3ModUploader.exe publish –title <name_of_your_mod> –description <short_description> –preview <preview_image> –content <path_of_your_mod>
- Successful publishing will create an "update_mod.bat" for you with the right values. You can use this, or modify it for your liking.
- Updating: Guild3ModUploader.exe update –mod <mod_id> –preview <preview_image> –content <path_of_your_mod>
